Abstract

The invention discloses a human-machine collaboration method and system based on **standardized cognitive protocols**. The system comprises: a **standardized cognitive protocol container**, configured to encapsulate a data body including a metadata header, an exclusive mantra parameter mapping set, and a physical self-consistency assertion predicate package, wherein the metadata header defines a tamper-proof multi-generation inheritance chain established based on cascading hash; a **meta-cognitive protocol compiler**, deployed in a secure computing environment, which adaptively translates and assembles exclusive mantras in the container into translated instruction streams embedded with concealed property right confirmation watermarks according to features and preferences of a target computing power engine; and an **outbound self-consistency assertion interceptor**, deployed in the secure computing environment, which performs self-consistency verification centered on logical entropy calculation and forbidden vocabulary filtering on raw output text streams generated by a large model, and triggers physical communication fusing if verification fails.

The invention eliminates rule interpretation ambiguity of heterogeneous large model engines, realizes multi-generation derivation, traceability and right confirmation of high-value Chuan Guang Shi cognitive property rights as well as low-threshold external auditing, and establishes a deterministic security filtering gateway at the computing power outbound site.
