Abstract

The present invention discloses a dynamic pricing and verification system and method based on result validation. In the system, a Price Limitation Gateway is deployed at the gateway control layer to maintain a three-tier state machine of trial, paid AI and human pay-by-result payment, and forcibly controls state transitions through a cumulative invocation counter. When transitioning to the human service tier, result indicators are calculated locally in an isolated sandbox, raw data is purged, and a desensitized result assertion proof signed by a hardware private key mixed with a Nonce is uploaded on-chain via an encrypted channel. After passing anti-replay and optimistic lock concurrency control verification, the clearing contract on the decentralized ledger triggers peer-to-peer lockstep settlement of programmable fiat currency directly connected to multi-party wallets when the result meets the standard, and returns escrow funds when the result fails to meet the standard. The system also automatically redirects and diverts invocation traffic to homologous sub-protocols and realizes cascaded profit sharing when the Chuan Guang Shi's active sessions exceed the limit. The present invention balances users' data sovereignty and the fairness of result settlement, and prevents system congestion and asynchronous double spending.
